| State 11 -> State 0           | State 10   | -> State 11 |

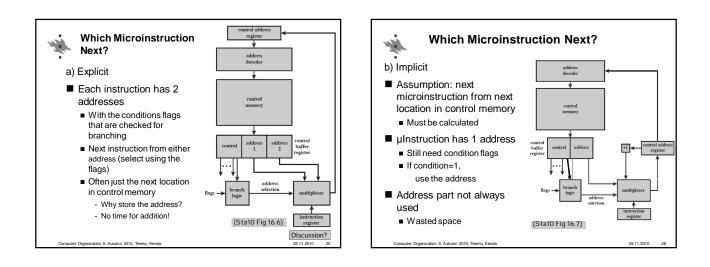

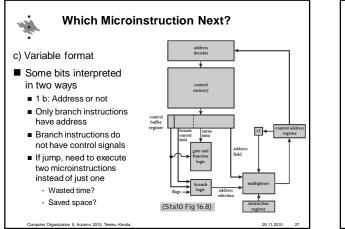

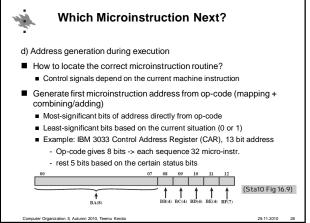

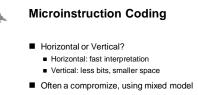

- e) Subroutines and residual control
- Microinstruction can set a special <u>return register</u> with 'return address'
  - No context, just one return allowed (one-level only)
  - No nested structure
  - Example: LSI-11, 22 bit microinstruction
    - Control memory 2048 instructions, 11 bit address
    - OP-code determines the first microinstruction address
    - Assumption, next is CAR ← CAR+1
    - Each instruction has a bit: subroutine call or not
    - Call:
    - Store return address (only the latest one available)
      Jump to the routine (address in the instruction)
    - Return: jump to address in return register

```
Computer Organization II, Autumn 2010, Teemu
```

- Microinstruction split to fields, each field is used for certain control signals
- Excluding signal combinations can be coded in the same field
  NOT: Reg source and destination, two sources one dest
- Coding decoded to control signals during execution
  One field can control decoding of other fields!
- Several shorter coded fields easier for implementation than one long field
  - Several simple decoders
